<tr>
<td>BC1.0</td>
<td>Mar 8, 2007</td>
<td>Terry Remple</td>
<td>First release</td>
</tr>
<tr>
<td>BC1.1</td>
<td>April 15, 2009</td>
<td>Terry Remple</td>
<td>Major updates to all sections. Added Data Contact Detect protocol, and Accessory Charger Adapter.</td>
</tr>
<tr>
<td>BC1.2</td>
<td>Oct 5, 2010</td>
<td>Terry Remple</td>
<td>Following items indicate changes from BC1.1 to BC1.2. References below to Section, Figures and Tables refer to BC1.2, unless BC1.1 is specifically indicated.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Adam Burns</td>
<td>1. Allow DCPs to output more than 1.5A. Allows Portable Devices (PDs) with switch mode chargers to draw more power. Section 4.4.1.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>2. Increase minimum CDP current to 1.5A. Without change, PDs had to draw less than 500mA, to avoid CDP shutdown. Table 5-2.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>3. Indicate that ( I_{CDP} ) max and ( I_{DCP} ) max limits of 5A come from USB 2.0, and are safety limits. Table 5-2 note 1.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>4. Allow PDs to draw up to 1.5A during HS chirp and traffic. Remove previous limits of 560mA and 900mA which was based on HS common mode ranges. Section 3.5.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>5. Require CDPs to support 1.5A during HS chirp and traffic. Affects CDP common mode range. Section 3.5.</td>
</tr>
<tr>
<td></td>
<td></td>

<td>27. Use session valid voltage range defined in EH and OTG Supplement rev 2.0. <a href="#">Section 3.2.2</a>.</td>
</tr>
<tr>
<td></td>
<td></td>
<td></td>
<td>28. Only devices that can operate stand-alone from internal battery power are allowed to use the Dead Battery Provision. <a href="#">Section 2.2</a>.</td>
</tr>
</tbody>
</table>
|   |   |   | 29. Allow compound PDs to draw Isus1p plus an
additional **Isusp** for each downstream port.  
Section 2.1.

30. Remove requirement for vendors to provide typical and maximum connect time for products having a Dead or Weak Battery for compliance testing.  
Section 2.

31. Remove references to no battery from Dead Battery Provision.  
Section 2.

32. Require PD using Dead Battery Provision to enable **VDP_SRC** from **TDBP_ATT_VDPSRC** after attach to **TDBP_VDPSRC_CON** before connect.  
Section 2.2.

33. Added DBP – Configured Clause, which allows PD with Dead Battery to draw **ICFG_MAX** for **TDBP_FUL_FNCTN** without having to pass USBCV.  
Section 2.3.

34. Note constraints when trying to charge from an OTG A-device.  
Section 1.6.

35. Change **IDP_SINK** and **IDM_SINK** range from 50-150uA to 25-175uA to ease PHY design.  
Table 5-2 note 1.

36. Allow USB 3.0 devices to implement BC charger detection protocols, and to use USB 3.0 ranges for **IUNIT** and **ICFG_MAX**.  
Section 1.7.

37. Rename previous ACA to Micro ACA, and define the Standard ACA.  
Section 6.

38. Add caps to OTG and Accessory Ports on ACA to support Attach Detection Protocol (ADP).  
Figure 6-3.

39. Change ACA ID resistance tolerances from 5% to 1% to ease PHY design.  
Table 5-3.

40. Remove requirements on ACA switching time(\(TACA_ID_VBUS\)) to ease ACA design.  
BC1.1 Section 6.5.

41. Add state diagram for PDs attached to ACA.  
Section 6.2.7.

42. Require PDs to limit current from ACA such that VBUS remains above **VACA_OPR**.  
Section 6.2.2.

43. Change minimum ACA operating voltage (\(VACA_OPR\)) from 3.0V to 4.1V.  
Table 5-1.

44. Remove requirement that ACA VBUS resistances (\(RACA_CHG_DIS\)) be greater than 10k when VBUS_CHG is greater than 6.5V.  
PDs are
responsible for protecting themselves against higher voltages on VBUS. BC1.1 Section 6.7.

45. Require ACAs to continue providing power to OTG device from Charging Port, even if ground offsets or USB reset cause D- to go below \( V_{DAT\_REF} \). Section 6.2.6.

46. Change charger shutdown recovery time \( (T_{SHTDWN\_REC}) \) from 2 seconds to 2 minutes. Table 5-5.

47. Indicate that ACA-Dock is required to pull D+ to \( V_{DP\_UP} \) with \( R_{DP\_UP} \) when VBUS is asserted. Section 3.2.4.4.

49. Improve readability by adding and updating drawings, re-structuring sections, and clarifying text.

1. **Introduction**

1.1 **Scope**

The Battery Charging Working Group is chartered with creating specifications that define limits as well as detection, control and reporting mechanisms to permit devices to draw current in excess of the USB 2.0 specification for charging and/or powering up from dedicated chargers, hosts, hubs and charging downstream ports. These mechanisms are backward compatible with USB 2.0 compliant hosts and peripherals.

1.2 **Background**

The USB ports on personal computers are convenient places for Portable Devices (PDs) to draw current for charging their batteries. This convenience has led to the creation of USB Chargers that simply expose a USB standard-A receptacle. This allows PDs to use the same USB cable to charge from either a PC or from a USB Charger.

If a PD is attached to a USB host or hub, then the USB 2.0 specification requires that after connecting, a PD must draw less than:
- 2.5 mA average if the bus is suspended
- 100 mA if bus is not suspended and not configured
- 500 mA if bus is not suspended and configured for 500 mA

If a PD is attached to a Charging Port, (i.e. CDP, DCP, ACA-Dock or ACA), then it is allowed to draw IDEV_CHG without having to be configured or follow the rules of suspend.

In order for a PD to determine how much current it is allowed to draw from an upstream USB port, there need to be mechanisms that allow the PD to distinguish between a Standard Downstream Port and a Charging Port. This specification defines just such mechanisms.

Since PDs can be attached to USB chargers from various manufacturers, it is important that all provide an acceptable user experience. This specification defines the requirements for a compliant USB charger, which is referred to in this spec as a USB Charger.

If a PD has a Dead or Weak Battery, then the Connect Timing Engineering Change Notice (ECN) issued by the USB-IF on the USB 2.0 spec allows that device to draw up to IUNIT while attached but not connected. The conditions associated with this ECN are contained in Section 2 of this specification, and are referred to as the Dead Battery Provision (DBP).

1.3 **Reference Documents**

The following specifications contain information relevant to the Battery Charging Specification.

- OTG and Embedded Host Supplement, Revision 2.0
- USB 2.0 Specification
- USB 3.0 Specification
1.4 Definitions of Terms

This section contains definitions for some of the terms used in this specification.

1.4.1 Accessory Charger Adaptor

An Accessory Charger Adaptor (ACA) is an adaptor which allows a single USB port to be attached to both a charger and another device at the same time.

The following terminology is used when referring to an ACA:

- ACA-A An ACA with ID resistance of RID_A
- ACA-B An ACA with ID resistance of RID_B
- ACA-C An ACA with ID resistance of RID_C

See Section 6 for details on an ACA.

1.4.2 ACA-Dock

An ACA-Dock is a docking station that has one upstream port, and zero or more downstream ports. The upstream port can be attached to a PD, and is capable of sourcing ICDP to the PD. An ACA-Dock signals it is an ACA-Dock to the PD by enabling VDM_SRC during USB idle, and by pulling ID to ground through a resistance of RID_A. See Section 3.2.4.4 for more details.

1.4.3 Attach versus Connect

This specification makes a distinction between the words "attach" and "connect". A downstream device is considered to be attached to an upstream port when there is a physical cable between the two.

A downstream device is considered to be connected to an upstream port when it is attached to the upstream port, and when the downstream device has pulled either the D+ or D- data line high through a 1.5 kΩ resistor, in order to enter Low-Speed, Full-Speed or High-Speed signaling.

1.4.4 Charging Downstream Port

A Charging Downstream Port (CDP) is a downstream port on a device that complies with the USB 2.0 definition of a host or a hub, except that it shall support the Charging Downstream Port features specified herein.

A CDP shall output a voltage of VDM_SRC on its D- line when it senses a voltage greater than VDAT_REF but less than VLGC on its D+ line when not connected to a peripheral. A CDP shall not output a voltage of VDM_SRC on its D- line from the time that the peripheral is connected, to the time that the peripheral is disconnected.

1.4.5 Charging Port

A Charging Port is a DCP, CDP, ACA-Dock or ACA.

1.4.6 Dead Battery Threshold

The Dead Battery Threshold is defined as the maximum charge level of a battery such that below this threshold, a device is assured of not being able to power up successfully.

A Dead Battery is defined as one that is below the Dead Battery Threshold.
1.4.7 Dedicated Charging Port
A Dedicated Charging Port (DCP) is a downstream port on a device that outputs power through a USB connector, but is not capable of enumerating a downstream device. A DCP shall source \( I_{DCP} \) at an average voltage of \( V_{CHG} \).

A DCP shall short the D+ line to the D- line.

1.4.8 Downstream Port
In this specification, a Downstream Port refers to either a Standard Downstream Port or a Charging Downstream Port.

1.4.9 Micro ACA
A Micro ACA is an ACA with a Micro-AB receptacle on the Accessory Port.

1.4.10 Portable Device
A PD as used in this specification is a device which is compliant with this specification and the USB 2.0 specification, and can draw charging current from USB.

1.4.11 Rated Current
The Rated Current of a Charging Port is the amount of current that a Charging Port can output and still maintain a VBUS voltage of \( V_{CHG} \). The Rated Current of a DCP is required to be within \( I_{DCP} \), and the rated current of a CDP or ACA-Dock is required to be within \( I_{CDP} \).

1.4.12 Standard ACA
A Standard ACA is an ACA with a Standard-A receptacle on the Accessory Port.

1.4.13 Standard Downstream Port
In this specification, a Standard Downstream Port (SDP) refers to a downstream port on a device that complies with the USB 2.0 definition of a host or hub. An SDP expects a downstream device with a good battery to draw less than 2.5 mA average when unconnected or suspended, up to 100 mA maximum when connected and not configured and not suspended, and up to 500 mA maximum if so configured and not suspended. A downstream device can be enumerated when it is connected to an SDP.

An SDP pulls the D+ and D- lines to ground through two 15 kΩ (typical) resistors.

An SDP may have the ability to sense when a PD is driving the D+ line to \( V_{DP\_SRC} \), and then manage its power states accordingly. PDs are required to drive D+ to \( V_{DP\_SRC} \) whenever they draw more than \( I_{SSUSP} \) while attached but not connected, as described in the Dead Battery Provision.

1.4.14 USB Charger
A USB Charger is a device with a DCP, such as a wall adapter or car power adapter.

1.4.15 Weak Battery Threshold
The Weak Battery Threshold is defined as the minimum charge level of a battery such that above this threshold, a device is assured of being able to power up successfully.
A Weak Battery is defined as one that is above the Dead Battery Threshold and below the Weak Battery Threshold. A device with a Weak Battery may or may not be able to power up a device successfully. A Good Battery is defined as one that is above the Weak Battery Threshold.

1.5 Parameter Values
Parameter names are used throughout this specification instead of parameter values. All parameter values are found in Section 5.

1.6 OTG Considerations
A PD with a Dead Battery cannot differentiate between a PC and an OTG A-device. Thus, a PD will treat both the same.

If an OTG A-device is connected to a PD with a dead battery, then the OTG A-device is under no obligation to provide any more current than it normally would to any device on its Targeted Peripheral List (TPL).

An OTG A-device is allowed to stop driving VBUS after a time of TA_WAIT_BCON (See OTG 2.0 Specification for value) while waiting for the B-device to connect. Thus, a PD with a Dead Battery may not have time for significant charging when attached to an OTG A-device, if it does not connect.

1.7 Super Speed Considerations
SuperSpeed ports defined in USB 3.0 are allowed to implement the charger detection mechanisms defined in this spec. When a PD detects it is attached to a SuperSpeed port, then $ICFG_{MAX}$ changes to 900mA, and $IUNIT$ changes to 150mA.

2. Dead Battery Provision
2.1 Background
The USB 2.0 specification allows a downstream device to draw a suspend current of up to $ISUSP$ from a SDP when the device is not connected or when the bus is suspended. If the bus is not suspended and the device is configured, then USB 2.0 allows a device to draw up to $ICFG_{MAX}$, depending on the configuration the host enables.

This limit of only $ISUSP$ when not connected can be problematic for PDs with a Dead Battery or a Weak Battery. Some PDs require more than $IUNIT$ for several seconds just to power up. Thus, PDs with Dead Batteries or Weak Batteries may not be able to power up when attached to an SDP if they can only draw $ISUSP$ when not connected.

USB 2.0 allows a PD that is a compound device to draw $ISUSP$ for each downstream port while attached but not connected or during suspend.

2.2 DBP – Unconfigured Clause
A PD with a Dead or Weak Battery is allowed to draw $IUNIT$ from a Downstream Port using the DBP while not configured, providing it behaves as follows:

- Reduces current to $ISUSP$ after timeout
  - If PD is not ready to connect and be enumerated within $T_{SVLD\_CON\_WKB}$ after attach, then it shall reduce its current to $ISUSP$
• Enables VDP_SRC when attached but not connected
  o PD shall enable VDP_SRC within TDBP_ATT_VDPSRC of attach
  o PD shall connect within TDBP_VDPSRC_CON of disabling VDP_SRC

• Uses current to power up and enumerate, or reach Weak Battery Threshold and enumerate, as soon as possible
  o PD shall not use the DBP current to perform unrelated tasks, such as:
    ▪ Charging beyond the Weak Battery Threshold
    ▪ Making a phone call
    ▪ Playing a song, video or game
    ▪ Establishing a wireless connection
  o Only devices that can operate stand-alone from internal battery power are allowed to use the DBP.

• Passes inrush test
  o PD with Dead or Weak Battery shall pass USB-IF compliance inrush test

The unconfigured state includes the time that the PD is attached and not connected, and the time that the PD is connected and not configured. A PD enters the configured state by receiving a SET_CONFIGURATION command from the host.

2.3 DBP – Configured Clause

A PD with a Dead or Weak Battery is allowed to draw its configured current, (which can be up to ICFG_MAX), from a Standard Downstream Port using the Dead Battery Provision (DBP) while configured, and not have to pass USBCV tests, providing it behaves as follows:

• Responds to received tokens
  o PD shall respond to any tokens addressed to it, with either a NAK or any other valid USB response

• Responds to USB reset
  o Upon receipt of USB reset, a PD shall reduce its current to IUNIT. PD is allowed to disconnect upon receiving a reset. While disconnected, PD is allowed to use the DBP – Unconfigured Clause.

• Responds to USB suspend
  o Upon receipt of USB suspend, PD shall either remain connected, and reduce its current to ISUSP, or it shall disconnect. While disconnected, the PD is allowed to use the DBP – Unconfigured Clause.

• Provides full USB functionality after timeout, or disconnects
  o After a time of TDBP_FUL_FNCTN from attach, a PD shall either remain connected and be able to pass USBCV, or it shall disconnect. While disconnected, the PD is allowed to use the DBP – Unconfigured Clause.

• Uses current to reach Weak Battery Threshold and provide full USB functionality as soon as possible
  o PD shall not use the DBP current to perform unrelated tasks, such as:
    ▪ Charging beyond the Weak Battery Threshold
    ▪ Making a phone call
    ▪ Playing a song, video or game
    ▪ Establishing a wireless connection
- Provides full USB functionality upon reaching Weak Battery Threshold
  - PD shall provide full USB functionality upon reaching Weak Battery Threshold if this occurs before \texttt{TDBP\_FUL\_FNCTN} after attach.

- PD informs user within \texttt{TDBP\_INFORM} of attach that it is charging and not available for other functions

3. Charging Port Detection

3.1 Overview

\textit{Figure 3-1} shows several examples of a PD attached to an SDP or Charging Port.

\begin{center}
\includegraphics[width=\textwidth]{system_overview.png}
\end{center}

\textit{Figure 3-1 System Overview}
In the first example, a Std-A to Micro-B cable is used to attach a PD to an SDP, CDP or DCP. In the second example, a DCP has a captive cable. This cable does not have wires for D+ or D-, but instead shorts the D+ and D- pins at the Micro-B plug.

In the third example, an ACA is required to have a captive cable that attaches to the Portable Device, and this cable is required to have wires for D+, D- and ID. The ACA is also required to have a port that can be attached to a DCP or CDP. The cabling for this port is described in Section 6.2.1.

In the fourth example, an ACA-Dock does not have a cable at all, but instead has a captive Micro-A plug. An ACA-Dock receives power from a Proprietary Charger, that is attached to the ACA-Dock through a proprietary cable.

3.2 Charger Detection Hardware

This section briefly describes the hardware used to do charger detection. The following sections provide more details of its operation.
3.2.1 Overview

Figure 3-2 shows the charger detection hardware for a PD.

![Charger Detection Hardware Diagram]

### Portable Device

- **VBUS Detect**
  - Detect when VBUS is asserted

- **Data Contact Detect**
  - Detect when data pins have made contact

- **Primary Detection**
  - Detects between SDP and DCP/CDP, or between ACA-Dock and ACA_A

- **Secondary Detection**
  - Detects between DCP and CDP

- **ACA Detection**
  - Detects between:
    - DCP/CDP/SDP
    - ACA-Dock/ACA_A
    - ACA_B
    - ACA_C

---

3.2.2 VBUS Detect

Each PD shall have a session valid comparator that detects when VBUS is greater than its internal session valid threshold. Its internal session valid threshold shall be within **VOTG_SESS_VLD**.
3.2.3 Data Contact Detect

3.2.3.1 Overview

Data Contact Detect (DCD) uses a current source, \texttt{IDP\_SRC}, to detect when the data pins have made contact during an attach event. A PD is not required to implement DCD. If a PD does not implement DCD, then it shall wait a time of \texttt{TDCD\_TIMEOUT} min after the attach event before starting Primary Detection.

DCD is able to detect data pin contact whenever a PD is attached to an SDP or CDP. The primary benefit of DCD is that it allows a PD to start Primary Detection as soon as the data pins have made contact, and then connect, without having to wait for a timer to expire. As per the USB Connect Timing ECN, a powered up USB device is required to connect to a USB host within \texttt{TSVLD\_CON\_PWD} of the attach event.

DCD is also able to detect data pin contact for most cases of a PD attached to a DCP or ACA. Cases where DCD may not work include:

- DCP with too much leakage current
- ACA with charger and FS or HS B-device on Accessory Port
- ACA-Dock
- PS2 port that pulls D+ high
- Proprietary chargers that pull D+ high

Since DCD does not work in all cases, a PD is required to proceed to Primary Detection within \texttt{TDCD\_TIMEOUT} max after the attach event if pin contact has not been detected on the D+ or ID pins. See Section 3.3.2.
3.2.3.2 Problem Description

USB plugs and receptacles are designed such that when the plug is inserted into the receptacle, the power pins make contact before the data pins make contact. This is illustrated in Figure 3-3.

As a result, when a PD is attached to an upstream port, the PD will detect VBUS before the data pins have made contact. The time between power pins and data pins making contact depends on how fast the plug is inserted into the receptacle. Delays of more than two hundred milliseconds have been observed.

The way that a PD distinguishes between a Charging Port and an SDP is to look at the data lines. If the PD does Primary Detection before the data pins have made contact, then the Primary Detection protocol is such that the PD will determine that it is attached to an SDP.

If a PD is attached to a DCP, and incorrectly determines that it is attached to an SDP, then the PD would draw ISUSP while waiting to be enumerated. Since a DCP will not enumerate the PD, the PD will not be able to charge.
3.2.3.3 Data Contact Detect, Not Attached

Figure 3-4 shows the case where the PD is not attached to a remote device.

The protocol for Data Contact Detect is as follows:

- PD detects VBUS asserted
- PD turns on $\text{IDP}_{\text{SRC}}$ and the D- pull-down resistor
- PD waits for D+ line to be low for a time of $\text{TDCD}_{\text{DBNC}}$
- PD turns off $\text{IDP}_{\text{SRC}}$ and D- pull-down resistor
When nothing is attached to the PD, the D+ line stays high. The minimum value of $I_{DP\_SRC}$ is such that it is able to hold D+ at $V_{LGC\_HI}$ for worst case leakages in the PD due to $R_{DAT\_LKG}$ and $V_{DAT\_LKG}$. 
3.2.3.4 Data Contact Detect, Standard Downstream Port

Figure 3-5 shows the case where the PD is attached to an SDP.

When the PD is attached to an SDP, the D+ line is pulled low by \( \text{RDP} \_\text{DWN} \) in the SDP. The maximum value of \( \text{IDP} \_\text{SRC} \) is such that \( \text{RDP} \_\text{DWN} \) pulls D+ to \( \text{VLGC} \_\text{LOW} \) for worst values of \( \text{RDAT} \_\text{LKG} \), \( \text{VDAT} \_\text{LKG} \), and \( \text{RDP} \_\text{DWN} \).
3.2.4 Primary Detection

Primary Detection is used to distinguish between an SDP and different types of Charging Ports. A PD is required to implement Primary Detection.

3.2.4.1 Primary Detection, DCP

Figure 3-6 shows how Primary Detection works when a PD is attached to a DCP.

![Diagram of Primary Detection, DCP](image-url)
During Primary Detection the PD shall turn on \texttt{VDP\_SRC} and \texttt{IDM\_SINK}. Since a DCP is required to short D+ to D- through a resistance of \texttt{RDCP\_DAT}, the PD will detect a voltage on D- that is close to \texttt{VDP\_SRC}.

A PD shall compare the voltage on D- with \texttt{VDAT\_REF}. If D- is greater than \texttt{VDAT\_REF}, then the PD is allowed to detect that it is attached to either a DCP or CDP. A PD is optionally allowed to compare D- with \texttt{VLGC} as well, and only determine that it is attached to a DCP or CDP if D- is greater than \texttt{VDAT\_REF}, but less than \texttt{VLGC}. The reason for this option is as follows.

PS2 ports pull D+/- high. If a PD is attached to a PS2 port, and the PD only checks for D- greater than \texttt{VDAT\_REF}, then a PD attached to a PS2 port would determine that it is attached to a DCP or CDP and proceed to draw \texttt{IDEV\_CHG}. This much current could potentially damage a PS2 port. By only determining it is attached to DCP or CDP if D- is less than \texttt{VLGC}, the PD can avoid causing damage to a PS2 port.

On the other hand, some proprietary chargers also pull D+/- high. If a PD is attached to one of these chargers, and it determined it was not attached to a charger because D- was greater than \texttt{VLGC}, then the PD would determine that it was attached to an SDP, and only be able to draw \texttt{ISUSP}.

The choice of whether or not to compare D- to \texttt{VLGC} depends on whether the PD is more likely to be attached to a PS2 port, or to a proprietary charger.
3.2.4.2 Primary Detection, CDP

Figure 3-7 shows how Primary Detection works when a PD is attached to a CDP.

A CDP is required to behave in either one of two ways when a remote device is not connected to it. The first way that a CDP is allowed to behave is to enable VDM_SRC within TCP_VDM_EN of a disconnect, and then disable VDM_SRC within TCP_VDM_DIS of a connect. When using this option, a CDP is not required to enable IDP_SINK, or to compare D+ to VDAT_REF.

The second way a CDP is allowed to behave is to compare D+ with VDAT_REF and VLGC. When D+ is greater than VDAT_REF and less than VLGC, the CDP shall enable VDM_SRC. When D+ is less than VDAT_REF...
or greater than $V_{LGC}$, the CDP shall disable $V_{DM\_SRC}$. Note that a CDP is required to compare D+ to $V_{LGC}$, in order to disable $V_{DM\_SRC}$ when the PD connects. See Section 3.4.2 for timing.

During Primary Detection the PD shall turn on $V_{DP\_SRC}$ and $I_{DM\_SINK}$. A PD shall compare the voltage on D- with $V_{DAT\_REF}$. If D- is greater than $V_{DAT\_REF}$, then the PD is allowed to determine that it is attached to either a DCP or CDP. A PD is optionally allowed to compare D- with $V_{LGC}$ as well, and only determine that it is attached to a DCP or CDP if D- is greater than $V_{DAT\_REF}$, but less than $V_{LGC}$. See Section 3.2.4.1 for more details.
3.2.4.3 Primary Detection, SDP

Figure 3-8 shows how Primary Detection works when a PD is attached to an SDP.

During Primary Detection the PD shall turn on VDP_SRC and IDM_SINK. When a voltage of VDP_SRC is applied to D+, an SDP will continue pulling D- low through RDM_DWN.

A PD shall compare the voltage on D- with VDAT_REF. If D- is less than VDAT_REF, then the PD is allowed to determine that it is attached to an SDP. A PD is optionally allowed to compare D- with VLGC as well, and determine that it is attached to an SDP if D- is greater than VLGC. See Section 3.2.4.1 for more details.
3.2.4.4 Primary Detection, ACA-Dock

Figure 3-9 shows how Primary Detection works when a PD that supports ACA Detection is attached to an ACA-Dock.

An ACA-Dock is a docking station that has one upstream port, and zero or more downstream ports. The upstream port can be attached to a PD, and is capable of sourcing $I_{ccp}$ to the PD.
When an ACA-Dock is powered, but nothing is attached to its upstream port, it is required to bias the pins on its upstream port as follows:

- **VBUS** <sup>VCHG</sup>
- **D+** <sup>VDP_UP</sup>
- **D-** <sup>VDM_SRC</sup>
- **ID** <sup>Rid_A</sup>
- **GND** <sup>GND</sup>

The VBUS pin is at **VCHG** because the ACA-Dock is ready to provide power to a PD. The ACA_Dock is required to pull D+ to **VDP_UP** through **Rdp_UP** because the VBUS pin is greater than **VOTG_SESS_VLD**.

An ACA-Dock is required to enable **VDM_SRC** whenever D+/ have been inactive (at idle J state) for a time of **TCP_VDM_EN**. An ACA-Dock is required to disable **VDM_SRC** within **TCP_VDM_DIS** of any activity on D+/-.

An ACA-Dock is required to present an impedance to ground on ID of **Rid_A** whenever it is powered. It is required to present an impedance to ground on ID of **Rid_FLOAT** when it is not powered.

When a PD that supports ACA detects the following conditions, it shall determine that it is attached to an ACA-Dock:

- **VBUS > VOTG_SESS_VLD**
- **D+ at VLGC_HI**
- **VDAT_REF < D- < VLGC**
- **ID at Rid_A**

Note that a PD attached to an ACA-Dock is required to compare D- with **VLGC**. If a PD were attached to an ACA that had a LS peripheral on its Accessory Port, then the ID pin of the PD would be pulled to ground through **Rid_A**, and the D- pin would be at **VLGC_HI** instead of **VDM_SRC**. In order to distinguish between an ACA with a LS device and an ACA-Dock, the PD is required to detect if D- is above or below **VLGC**.

The **VDP_SRC** in the PD shall be such that D+ remains at a logic high while the ACA-Dock is pulling D+ to **VDP_UP** through **Rdp_UP**. The reason for this is so that the ACA-Dock does not detect activity on D+, which could cause it to turn off its **VDM_SRC** before the PD completes its Primary Detection.
3.2.4.5 Primary Detection, Micro ACA

Figure 3-10 shows how Primary Detection works when a PD that supports ACA Detection is attached to a Micro ACA.

A PD that supports ACA Detection is required to monitor the resistance on the ID pin whenever VBUS is greater than \texttt{VOTG_SESS_VLD}. If the ID resistance is \texttt{RID_B} or \texttt{RID_C}, then the PD knows that it is attached to an ACA. If the ID resistance is \texttt{RID_A}, then the PD could be attached to either an ACA with a B-device on its Accessory Port, or to an ACA-Dock.
In order to distinguish between an ACA with an B-device, and an ACA-Dock, the PD shall compare the voltage on D- with $VDAT_{REF}$ and $VLGC$ to detect what it is attached to as follows:

- $D- < VDAT_{REF}$  
  ACA with FS B-device on Accessory Port
- $VDAT_{REF} < D- < VLGC$  
  ACA-Dock
- $VLGC < D-$  
  ACA with LS B-device on Accessory Port

The PD shall do the above detection on D- after attach, and before connect, as shown in the Good Battery Algorithm.

After doing Primary Detection, a PD that supports ACA Detection shall continue to monitor the ID line. If this resistance changes, the PD shall respond according to the state machine defined in Section 6.2.7.

An ACA is required to do a form of Primary Detection over the DP_CHG and DN_CHG lines to detect if a Charging Port is attached to the ACA Charger Port. This detection is done with the lines highlighted in yellow, and is described in Section 6.2.6.

### 3.2.5 Secondary Detection

Secondary Detection can be used to distinguish between a DCP and a CDP. PDs that are not ready to be enumerated within $TSVLD_{CON\_PWD}$ of detecting VBUS are required to implement Secondary Detection. PDs that are ready to be enumerated are allowed to bypass Secondary Detection. See Section 3.3.2 on Good Battery Algorithm.
3.2.5.1 Secondary Detection, DCP

Figure 3-11 shows how Secondary Detection works when a PD is attached to a DCP.

During Secondary Detection, a PD shall output \textit{VDM\_SRC} on D-, turn on \textit{IDP\_SINK}, and compare the voltage on D+ to \textit{VDAT\_REF}. Since a DCP is required to short D+ to D- through a resistance of \textit{RDCP\_DAT}, the voltage on D+ will be close to \textit{VDM\_SRC}, which is above \textit{VDAT\_REF}.
If a PD detects that D+ is greater than \( \text{VDAT\_REF} \), it knows that it is attached to a DCP. It is then required to enable \( \text{VDP\_SRC} \) or pull D+ to \( \text{VDP\_UP} \) through \( \text{RDP\_UP} \), as defined in the Good Battery Algorithm in Section 3.3.2.

A PD is not required to compare D+ to \( \text{VLGC} \) during Secondary Detection.

### 3.2.5.2 Secondary Detection, CDP

Figure 3-12 shows how Secondary Detection works when a PD is attached to a CDP.
During Secondary Detection, a PD shall output \textit{VDM\_SRC} on D-, turn on \textit{IDP\_SINK}, and compare the voltage on D+ to \textit{VDAT\_REF}. Since a CDP does not short D+ to D-, the voltage on D+ will be close to ground, which is below \textit{VDAT\_REF}.

If a PD detects that D+ is less than \textit{VDAT\_REF}, it knows that it is attached to a CDP. It is then required to turn off \textit{VDP\_SRC} and \textit{VDM\_SRC}, as shown in the Good Battery Algorithm in Section 3.3.2, and is allowed to draw \textit{IDEV\_CHG}.

A PD is not required to compare D+ to \textit{VLGC} during Secondary Detection.

\subsection*{3.2.6 ACA Detection}

ACA Detection allows a PD to detect when it is attached to an ACA, and to detect what type of device is attached to the ACA Accessory Port. See Section 6 for a description of the ACA.

A PD is not required to support ACA Detection. Only PDs that have a Micro-AB receptacle can support ACA Detection, since the ACA OTG Port has a captive cable terminating in a Micro-A plug.

PDs that support ACA Detection are required to implement the Good Battery Algorithm defined in Section 3.3.2.
Figure 3-13 shows how ACA Detection works when a PD is attached to a Micro ACA.

A PD detects the presence of an ACA by sensing the resistance on the ID pin. There are five different resistance values that shall be detected during ACA Detection, namely: \texttt{RID}_GND, \texttt{RID}_C, \texttt{RID}_B, \texttt{RID}_A and \texttt{RID}_FLOAT. PDs that support ACA Detection shall monitor the ID resistance during the entire time that VBUS is asserted, and respond according to the PD State Machine in Section 6.2.7.
3.3 Charger Detection Algorithms

3.3.1 Weak Battery Algorithm

Figure 3-14 shows an example charger detection algorithm for a PD with a Weak Battery. Other algorithms are allowed, providing they comply with the DBP.

![Weak Battery Algorithm Diagram]

Figure 3-14 Weak Battery Algorithm
A PD is required to have internal voltage thresholds that lie within $\text{VOTG\_SESS\_VLD}$, $\text{VDAT\_REF}$ and $\text{VLGC}$. In the above algorithm, a PD compares VBUS, D+ and D- with its internal thresholds. It does not compare VBUS, D+ and D- with the min or max value of $\text{VOTG\_SESS\_VLD}$, $\text{VDAT\_REF}$ or $\text{VLGC}$.

In the above example, a PD with a Weak Battery detects VBUS greater than $\text{VOTG\_SESS\_VLD}$, and applies a voltage of $\text{VDP\_SRC}$ on the D+ pin. If the voltage on D- is greater than its $\text{VDAT\_REF}$, or if the ID pin is not floating, the PD is allowed to draw $\text{IDEV\_CHG}$. Else the PD is allowed to draw $\text{IUNIT}$.

The $\text{VLGC}$ term shown in magenta could be added to prevent a PD from charging from PS2 ports and some proprietary chargers.
3.3.2 Good Battery Algorithm

Figure 3-15 shows the charger detection algorithm that a PD with a Good Battery is required to implement.

A PD shall implement the Good Battery Algorithm when attached to an SDP or Charging Port. A PD is allowed to include additional branches for detecting devices or ports other than an SDP or Charging Port. Any such branches shall not cause additional activity on D+/- and/or ID that would interfere or be confused with the next expected event when the PD is attached to an SDP or Charging Port. Branches are also allowed after any final step in detection, and these branches may include additional activity on D+/- and/or ID, except that when a PD is attached to a DCP, it shall maintain D+ greater than VDAT_REF while VBUS is asserted.
Upon detecting VBUS greater than its VOTG_SESS_VLD threshold, a PD shall start a timer with a timeout value of TDCD_TIMEOUT. A PD that supports DCD is allowed to enable its IDP_SRC and monitor for D+ being at VLGC_LOW for TDCD_DBNC. A PD that supports ACA Detection is allowed to monitor for ID not floating for TDCD_DBNC. If the DCD timer expires before the D+ or ID conditions are detected, the PD shall proceed to Primary Detection.

If a PD detects that ID is not floating for a time of TDCD_DBNC, then it is allowed to proceed directly to one of the ACA states, without having to do Primary Detection and without having to assert VDP_SRC.

During Primary Detection, a PD shall enable VDP_SRC, and compare D- with VDAT_REF. A PD may optionally compare D- with VLGC to avoid damaging a PS2 port. See Section 3.2.4.1. A PD that supports ACA Detection is required to detect the resistance on the ID line.

If a PD detects that it is attached to either a DCP or CDP during Primary Detection, and it is ready to be enumerated, then it is allowed to take the branch where it connects. If a PD is not ready to be enumerated, then it is required to do Secondary Detection.

During Secondary Detection, the PD shall disable VDP_SRC, enable VDM_SRC and compare D+ with VDAT_REF. If D+ is greater than VDAT_REF, then the PD is attached to a DCP. The PD shall disable VDM_SRC, and either enable VDP_SRC or pull D+ to VDP_UP through RDP_UP.

If D+ is less than VDAT_REF, then the PD is attached to a CDP. The PD shall disable VDM_SRC, and leave both D+ and D- low until it is ready to connect and be enumerated.

A PD that is attached to a DCP shall either enable VDP_SRC or pull D+ high within TSVLD_CON_PWD of attach.

A PD that supports ACA Detection is required to monitor the resistance on the ID line. If a resistance of RID_A is detected, then the PD shall compare D- with both VDAT_REF and VLGC, to determine if it is attached to an ACA-Dock or an ACA-A. See Section 3.2.4.4 for more details.
3.4 Charger Detection Timing

3.4.1 Data Contact Detect Timing

To initiate Data Contact Detect, the PD shall enable IDP_SRC and either IDM_SINK or RDM_DWN. When the PD detects that the D+ line has been low for a time of TDCD_DBNC, then the PD knows that the data pins have made contact.

Figure 3-16 shows the timing associated with Data Contact Detect (DCD) when pins make contact after DCD starts.

![Figure 3-16 DCD Timing, Contact After Start](image-url)
Figure 3-17 shows the timing associated with Data Contact Detect when pins have made contact before DCD starts.

Data pins have already made contact

Figure 3-17  DCD Timing, Contact Before Start
Figure 3-18 shows the timing associated with Data Contact Detect when contact is not detected.
3.4.2 Detection Timing, CDP

Figure 3-19 shows the timing associated with Primary and Secondary Detection when a PD is attached to a CDP, for the case where the CDP compares D+ to VDAT_REF and VLGC, and enables VDM_SRC accordingly. A CDP is also allowed to leave VDM_SRC enabled while a remote device is not connected. See Section 3.2.4.2 for more details.

![Figure 3-19 Detection Timing, CDP](image)
Notes:

1) The timing for a LS PD is the same as shown above, except that a LS PD will pull D- high, instead of D+.

**Figure 3-19** shows the Primary and Secondary Detection timing for a PD attached to a CDP. During Primary Detection, the PD turns on VDP_SRC and IDM_SINK. The CDP is required to have VDM_SRC on D- within a time of TVDMSRC_EN from when D+ is above VDAT_REF. After a time of TVDPSRC_ON, the PD is allowed to check the status of the D- line. If D- is above VDAT_REF (and optionally below VLGC, see Section 3.2.4.1) then the PD is attached to a Charging Port, and is allowed to draw IDEV_CHG.

In order to do Secondary Detection, the PD is required to disable VDP_SRC and IDM_SNK, and enable VDM_SRC and IDP_SINK. After a time of TVDMSRC_ON, the PD is allowed to check the status of the D+ line. Since a CDP does not source a voltage on D+, D+ is below VDAT_REF and the PD is attached to a CDP.

If the PD was powered up at the time VBUS was detected, then it shall connect within a time of TSVLD_CON_PWD. The CDP shall disable IDP_SINK within TCON_IDPSNK_DIS of detecting the connect.

### 3.5 Ground Current and Noise Margins

As shown in Figure 7-47 of the USB 2.0 specification, a current of 100 mA through the ground wire of a USB cable can result in a voltage difference of 25 mV between the host ground and the device ground. This ground difference has the effect of reducing noise margins for both signaling and charger detection.

The maximum current that a PD is allowed to draw from a CDP is IDEV_CHG. A PD that draws more than ICFG_MAX from a CDP is required to support LS, FS, HS and chirp signaling when the local ground is VGND_OFFSET max higher than the remote ground. A host port that grants the CDP handshake is required to support LS, FS, HS and chirp signaling when the local ground is VGND_OFFSET max lower than the remote ground.

When the ground offset is VGND_OFFSET max, the PD and CDP are required to have a greater common mode range than what is called out in USB 2.0.
4. Charging Port and Portable Device Requirements

This section describes the requirements for the following:

- Charging Downstream Port (CDP)
- ACA-Dock
- Dedicated Charging Port (DCP)
- Accessory Charger Adapter (ACA)
- Portable Device (PD)

4.1 Charging Port Requirements

The following requirements apply to all types of Charging Ports, including CDP, ACA-Dock, DCP and ACA.

4.1.1 Overshoot

The output voltage of a Charging Port shall not exceed $V_{CHG\_OVRSHT}$ for any step change in load current, nor when the Charging Port is powered on or off.

4.1.2 Maximum Current

The output current of a Charging Port shall not exceed $I_{CDP\_max}$ under any condition.

4.1.3 Detection Renegotiation

A downstream port is allowed to act as an SDP, CDP or DCP, and to change between these roles. In order to force an attached PD to repeat the charging detection procedure, a downstream port is required to:

- stop driving VBUS
- allow VBUS to drop to less than $V_{BUS\_LKG}$
- wait for a time of $T_{VBUS\_REAPP}$
- start driving VBUS

4.1.4 Shutdown Operation

If the current drawn by a PD causes a Charging Port to go outside of its Required Operating Range, then the Charging Port is allowed to shut down. All types of shut down are allowed outside the Required Operating Range of a Charging Port, including:

- Turning off VBUS
- Constant current limiting
- Foldback current limiting

4.1.5 Failure Voltage

The output voltage of a Charging Port shall remain within $V_{CHG\_FAIL}$ for any single point failure in the Charging Port.

4.1.6 Multiple Ports

For a device with multiple Charging Ports, each Charging Port shall stay within its Required Operating Range regardless of the operation of the other Charging Ports.
4.2 Charging Downstream Port

The following requirements apply to a CDP.

4.2.1 Required Operating Range

A CDP shall output a voltage of $V_{CHG}$ for all currents less than $I_{CDP\ min}$. The voltage on VBUS is averaged over a time of $TV_{BUS\ AVG}$. For load currents greater than $I_{CDP\ min}$, a CDP is allowed to shut down. Once in shutdown, the requirements in Section 4.1.4 apply.

Figure 4-1 shows several example load curves for a CDP. Load curves are required to cross the line at $I_{CDP\ min}$ within a voltage range of $V_{CHG}$. Load curves that cross the line at $V_{CHG}$ min for currents less than $I_{CDP\ min}$ are not allowed.

4.2.2 Shutdown Operation

If a CDP goes into shutdown during a current overload condition, it shall recover and output a voltage of $V_{CHG}$ within a time of $TSHTDWN\ REC$ when the current overload condition has been removed.
4.2.3 Undershoot
The output voltage of a CDP shall be within $V_{CHG\_UNDSHT}$ for any step change in load currents that are less than $I_{CDP\_min}$.

4.2.4 Detection Signaling
A CDP is required to behave in either one of two ways when a remote device is not connected to it. The first way that a CDP is allowed to behave is to enable $V_{DM\_SRC}$ within $TCP\_VDM\_EN$ of a disconnect, and then disable $V_{DM\_SRC}$ within $TCP\_VDM\_DIS$ of a connect. When using this option, a CDP is not required to enable $IDP\_SINK$, or to compare D+ to $V_{DAT\_REF}$.

The second way a CDP is allowed to behave is to compare D+ with $V_{DAT\_REF}$ and $VLGC$. When D+ is greater than $V_{DAT\_REF}$ and less than $VLGC$, the CDP shall enable $V_{DM\_SRC}$. When D+ is less than $V_{DAT\_REF}$ or greater than $VLGC$, the CDP shall disable $V_{DM\_SRC}$. See Section 3.4.2 for timing.

4.2.5 Connector
A CDP shall have a Standard-A receptacle.

4.3 ACA-Dock
The following requirements apply to the upstream port of an ACA-Dock.

4.3.1 Required Operating Range
An ACA-Dock shall have the same Required Operating Range as a CDP.

4.3.2 Undershoot
An ACA-Dock shall comply with the same undershoot requirements as a CDP.

4.3.3 Detection Signaling
When a PD is attached to an ACA-Dock, the PD acts as host while drawing current from VBUS. This is similar to the case where a PD is attached to an ACA with a peripheral on the Accessory Port.

To inform the PD that it should act as host and draw current, both the ACA-Dock and the ACA are required to pull the ID pin to ground through a resistance of $R_{ID\_A}$.

An ACA-Dock is required to provide $I_{CDP}$ to the PD, whereas an ACA is required to provide $I_{DCP}$, and this must be shared between the PD and whatever is on the Accessory Port. To inform the PD that it is attached to an ACA-Dock as opposed to an ACA, the ACA-Dock shall output a voltage of $V_{DM\_SRC}$ on D- as follows:

- ACA-Dock shall start outputting $V_{DM\_SRC}$ if D+/- are at idle J for a time of $TCP\_VDM\_EN$
- ACA-Dock shall stop outputting $V_{DM\_SRC}$ within $TCP\_VDM\_DIS$ of any USB activity on D+/-

4.3.4 Connector
An ACA-Dock shall have a Micro-A plug that can be mated to the Micro-AB receptacle of a PD.
4.4 Dedicated Charging Port

The following requirements apply to a DCP.

4.4.1 Required Operating Range

A DCP shall output a voltage of \( V_{\text{CHG}} \) for all currents less than \( I_{\text{DCP}} \) min. The voltage on VBUS is averaged over a time of \( T_{\text{VBUS\_AVG}} \).

A DCP shall not shut down if the load current is less than \( I_{\text{DEV\_CHG}} \) and the load voltage is greater than \( V_{\text{DCP\_SHTDWN}} \). A DCP is allowed to shut down for load currents greater than \( I_{\text{DEV\_CHG}} \) max, or for load voltages less than \( V_{\text{DCP\_SHTDWN}} \). Once in shutdown, the requirements in Section 4.1.4 apply.

Figure 4-2 shows several example load curves. DCP load curves are required to cross the constant current line at \( I_{\text{DEV\_CHG}} \) max, or the constant voltage line at \( V_{\text{DCP\_SHTDWN}} \). A DCP is not allowed to shut down in the Required Operating Range.

![Figure 4-2 DCP Required Operating Range](image-url)
4.4.2 Undershoot

For step changes in load current from \textit{IDCP\_LOW} to \textit{IDCP\_MID}, or from \textit{IDCP\_MID} to \textit{IDCP\_HI}, the undershoot voltage of a DCP shall be \textit{VCHG\_UNDSHT}. DCPs are required to meet this requirement for load steps from mid to hi that occur \textit{TDCP\_LD\_STP} after the transition from low to mid. The duration of the undershoot shall be \textit{TDCP\_UNDSHT}.

For step changes in load current from \textit{IDCP\_LOW} to \textit{IDCP\_HI}, the output voltage of a DCP is allowed to drop to the load voltage of the attached PD for a time of \textit{TDCP\_UNDSHT}. After this time, the output voltage of a DCP shall be at \textit{VCHG} for load currents less than \textit{IDCP} min.

4.4.3 Detection Signaling

A DCP shall have an impedance between D+ and D- of \textit{RDCP\_DAT}.

The leakage current on the D+/- pins of a DCP shall be less than or equal to the leakage current that would occur from two resistances of \textit{RDAT\_LKG} tied to a voltage of \textit{VDAT\_LKG}. See Figure 3-6.

The capacitance between the D+/- pins and ground of a DCP shall be \textit{CDCP\_PWR}.

4.4.4 Connector

A DCP shall have a Standard-A receptacle, or a captive cable terminated with a Micro-B plug.

4.5 Accessory Charger Adapter

The following requirements apply to an ACA with a DCP or CDP on its Charger Port.

4.5.1 Required Operating Range

The Required Operating Range for the OTG Port of an ACA is affected by the following factors:

- Device on Charger Port (DCP or CDP)
- Current drawn from Accessory Port
  - \textit{RACA\_CHG\_OTG}
  - \textit{VACA\_OPR}

The current available on the OTG Port is determined by how much current is supplied to the Charger Port, and how much current is being drawn from the Accessory Port. The voltage available on the OTG Port is determined by the voltage at the Charger Port, the current being drawn from the OTG and Accessory Ports, and \textit{RACA\_CHG\_OTG}. ACA operation is only required if for Charger Port voltages in the range of \textit{VACA\_OPR}.

4.5.2 Undershoot

An ACA with a DCP or CDP on its Charger Port shall comply with the same undershoot requirements as a DCP.

4.5.3 Detection Signaling

An ACA shall pull the ID pin of the OTG port to ground through one of the following resistances, as specified in Section 6:

- \textit{RID\_GND}, \textit{RID\_C}, \textit{RID\_B}, \textit{RID\_A}, \textit{RID\_FLOAT}

An ACA shall connect the data pins of the OTG Port directly to the data pins of the Accessory Port.
4.5.4 Connector
An ACA shall have a captive cable terminated with a Micro-A plug on its OTG Port.

4.6 Portable Device
The following requirements apply to a PD.

4.6.1 Allowed Operating Range
A PD shall not draw more than $I_{DEV\_CHG\_max}$ from a Charging Port. A PD shall not pull the output voltage of a Charging Port below $V_{DCP\_SHTDWN\_max}$. Figure 4-3 shows the Allowed Operating Range for a PD.

![Figure 4-3 Portable Device Allowed Operating Range](image)

Notes:
1) As per USB 2.0 section 7.2.2, the voltage on VBUS can drop from 4.75V at the upstream port down to 4.5V at the downstream port, due to resistive losses in the cable and connectors.

4.6.2 Detection Signaling
All PDs shall implement the following detection features:

- DCD timer ($T_{DCD\_TIMEOUT}$)
• Primary Detection
  o To detect between DCP, CDP and SDP
  o Compare D- to \text{VDAT\_REF} during Primary Detection

PDs are allowed, but not required, to implement the following detection features:

• DCD, using \text{IDP\_SRC}
• Compare D- to \text{VLGC} during Primary Detection
• Secondary Detection
• ACA Detection

4.6.3 Detection Renegotiation

To restart the charger detection procedure, a downstream port is allowed to remove and then re-assert power on VBUS. See Section 4.1.3. In order to detect this drop in VBUS, a PD shall discharge VBUS to less than \text{VBUS\_LKG} within \text{TVLD\_VLKG} whenever VBUS is removed.

A PD is allowed to disconnect and repeat the charger detection process multiple times while attached. The PD is required to wait for a time of at least \text{TCP\_VDM\_EN} max between disconnecting and restarting the charger detection process.

4.6.4 Connector

A PD that mates with an ACA-Dock or ACA shall have a Micro-AB receptacle.
## 5. Parameter Values

This section lists the values of parameters defined in this specification.

Notes
1) The maximum current is for safety reasons, as per USB 2.0 section 7.2.1.2.1.
2) If a PD is attached to a SuperSpeed port, then ICFG_MAX is 900mA.
3) For source currents less than IDM_SINK min, the D+ current sink is required to pull the D+ voltage to VDAT_SINK. For D+ voltages less than VLGC max, the D+ current sink shall not sink more than IDM_SINK max. The same requirements apply to IDM_SINK and D-.
4) IUNIT is averaged over 250ms. If a PD is attached to a SuperSpeed port, the IUNIT is 150mA.

Notes
1) The ACA shall meet this parameter requirement when VBUS_CHG is at VACA_OPR.
2) The ACA shall meet this parameter requirement when its ID_OTG pin is at VDAT_LKG. When detecting these resistances, an OTG device shall allow for an additional leakage current of IID_LKG_CONT due to contamination.
3) The ACA shall meet this parameter requirement when its VBUS_CHG pin is at VBUS_LKG.
4) Nominal values for these resistors are RID_A = 124k, RID_B = 68k and RID_C = 36.5k

6. Accessory Charger Adapter

6.1 Introduction

As PDs get smaller, it becomes more desirable for the PD to only have one external connector. If the only connector a device has is a USB connector, then a problem arises when the user wants to attach the device to a charger at the same time as it is already attached to something else.

For example, consider a user in a car with a cell phone that is attached to a headset. If the phone battery goes low, the user would like to charge the phone, and at the same time continue to talk through the headset. If the phone has only one connector, it is not possible to attach both a headset and a charger to the phone through the same connector.

Another example would be as follows. Consider a PD that has a single connector, which can also act as a handheld PC. When such a device is put into an ACA-Dock, it would act as a host to various USB peripherals, such as a hub, keyboard, mouse, printer, etc. However, while in the ACA-Dock, the device should also be able to charge at the same time.

The purpose of this section is to describe a method that allows a single USB port to be attached to both a charger and another device at the same time. This method makes use of an Accessory Charger Adapter (ACA), as shown in Figure 6-1.

![Figure 6-1 Accessory Charger Adapter](image)

An ACA has the following three ports:

- OTG Port
- Accessory Port
- Charger Port

The OTG Port shall have a captive cable that terminates with a Micro-A plug. Only OTG devices (ie those with a Micro-AB receptacle) can be attached to the OTG Port.
Accessories attached to the Accessory Port can communicate with the OTG device using normal USB signaling.

The Charger Port allows the ACA to be attached to a Charging Port. Power from the Charger Port is available to both the OTG device and the accessory. An ACA is required to label the Charger Port as Charger Only. The reason for this is that the ACA does not support USB communication between the OTG Port and the Charger Port. The Charger Port is only used for power. An ACA is also required to provide an indicator that shows when the Charger Port is able to provide power to the OTG and Accessory Ports.

There are two types of ACAs:

- Micro ACA
- Standard ACA

A Micro ACA has a Micro-AB receptacle on the Accessory Port, and can be attached to either an A-device or B-device. A Standard ACA has a Standard-A receptacle on the Accessory Port, and can only be attached to a B-device.

### 6.2 Micro ACA

#### 6.2.1 Micro ACA Ports

*Figure 6-2* shows the ports of a Micro ACA.

![Figure 6-2 Micro ACA Ports](image)

Various cables can be used to attach the Accessory Port of a Micro ACA to an accessory, including:

- Micro-A to Micro-B
- Micro-A to captive
- Micro-B to Standard-A
- Micro-B to Micro-A
A Micro ACA shall have one of the following mechanical interfaces for its Charger Port:
- Micro-B receptacle
- Captive cable terminating in a Standard-A plug
- Captive cable terminating in a charger

### 6.2.2 Micro ACA Connectivity Options

Table 6-1 shows the different combinations of devices that can be attached to each Micro ACA port, and provides comments on their operation.

</tbody>
</table>

An ACA does not allow data communication through the Charger Port. The ACA only allows charging from the Charger Port when a Charging Port is attached. It does not allow charging from the Charger Port whenever an SDP or an OTG device is attached.

In the case where both an OTG device and a B-device are charging from the Charger Port, it is not necessary to support SRP, since VBUS is already asserted at both the OTG Port and Accessory Port.

The OTG device is required to limit the current it draws from the ACA such that VBUS_OTG remains above $V_{ACA\_OPR}$ min.
6.2.3 Micro ACA Architecture

Figure 6-3 shows the architecture of a Micro ACA.

The Accessory Switch allows current to flow between VBUS_OTG and VBUS_ACC. The Charger Switch allows current to flow from VBUS_CHG and VBUS_OTG. The Adapter Controller performs several functions. These functions include:

- sensing the state of the ID_ACC pin, (grounded or floating)
- outputting a state onto the ID_OTG pin, (RID_GND, RID_A, RID_B, RID_C or RID_FLOAT)
- using the DP_CHG and DN_CHG pins to detect if a Charging Port is attached to the Charger Port
- sensing the voltage on the VBUS_ACC pin
- controlling the Charger and Accessory Switches
6.2.4 Micro ACA Modes of Operation

The operation of the Micro ACA is shown in Table 6-2, and is described below. The table assumes that an OTG device is always attached to the OTG Port.

</tbody>
</table>

Notes

1) Open refers to the high impedance state of the switch. Closed refers to the low impedance state of the switch.

In rows 5 and 7, a Charging Port is attached to the Micro ACA Charger Port, and either nothing is attached to the Accessory Port, or an A-device that is not asserting VBUS is attached to the Accessory Port. The ID resistance of RID_B indicates to the OTG device that it is allowed to charge, and that it is allowed to initiate SRP. The OTG device is not allowed to connect, (that is, leave DP_OTG asserted). The reason for this is that if an A-device is on the Accessory Port and is not asserting VBUS, then the USB spec requires the data lines remain at a logic low.

In row 8, a Charging Port is attached to the Micro ACA Charger Port, and an A-device that is asserting VBUS is attached to the Accessory Port. The ID resistance of RID_C indicates to the OTG device that it is allowed to charge, and that it is allowed to connect. However, it is not allowed to do SRP, since the A-device is already asserting VBUS.

In row 6, a Charging Port is attached to the Micro ACA Charger Port, and a B-device is attached to the Accessory Port. The ID resistance of RID_A indicates to the OTG device that it is allowed to charge, and that it should default to acting as host.
6.2.5 Implications of not Supporting Micro ACA Detection

The OTG supplement only defines the floating and ground states on the ID pin. The floating state is any impedance greater than 1M, and the ground state is any impedance less than 10Ω. Since the \( \text{Rid}_A, \text{Rid}_B \) and \( \text{Rid}_C \) resistances are between the floating and ground resistance values, an OTG device that does not support ACA detection could interpret any of these values as either floating or ground.

If an OTG device interpreted the \( \text{Rid}_A \) resistance as floating, then:
- It would not be aware of the opportunity to draw \( \text{Idev}_\text{CHG} \) from VBUS
- It would default to peripheral, when it should default to host

If an OTG device interpreted the \( \text{Rid}_B \) resistance as grounded, then:
- It would try to drive VBUS_OTG at the same time as the ACA was driving VBUS_OTG
- It would default to host, when it should default to peripheral

If an OTG device interpreted the \( \text{Rid}_B \) resistance as floating, then:
- It would not be aware of the opportunity to draw up to \( \text{Idev}_\text{CHG} \) from VBUS
- It would not be aware of the opportunity to do SRP
- It would be required to connect, and potentially violate the USB back-drive voltage spec

If an OTG device interpreted the \( \text{Rid}_C \) resistance as grounded, then:
- It would try to drive VBUS_OTG at the same time as the ACA was driving VBUS_OTG
- It would default to host, when it should default to peripheral

If an OTG device interpreted the \( \text{Rid}_C \) resistance as floating, then:
- It would not be aware of the opportunity to draw up to \( \text{Idev}_\text{CHG} \) from VBUS

6.2.6 Micro ACA Requirements

A Micro ACA Charger Port shall draw less than \( \text{ISusp} \) when anything other than a Charging Port is attached to it.

A Micro ACA shall draw less than \( \text{ISusp} \) when a Charging Port is attached to the ACA Charger Port and nothing is attached to the OTG Port or Accessory Port.

The resistance between the VBUS_CHG and VBUS_OTG pins of an ACA shall be \( \text{Raca}_\text{CHG_OTG} \) when the Charger Switch is closed in Table 6-2, and the voltage on VBUS_CHG is at \( \text{Vaca}_\text{OPR} \).

The resistance between the VBUS_CHG and VBUS_ACC pins of an ACA shall be \( \text{Raca}_\text{CHG_ACC} \) when the Accessory Switch is closed in Table 6-2, and the voltage on VBUS_CHG is at \( \text{Vaca}_\text{OPR} \).

The resistance between the VBUS_OTG and VBUS_ACC pins of an ACA shall be \( \text{Raca}_\text{OTG_ACC} \) when the Accessory Switch is closed in Table 6-2, and the voltage on VBUS_OTG is at \( \text{Vaca}_\text{OPR} \).

The resistance between the internal ground of the Micro ACA and the ground pin of a Micro-AB receptacle attached to the OTG port of an ACA shall be \( \text{Rotg}_\text{ACA_GND} \). This requirement limits the difference between OTG and ACA ground under conditions of high charging current. This in turn allows the OTG device to reliably detect the ACA ID resistance under conditions of high charging current.

When a Micro ACA detects VBUS_CHG asserted, it shall output \( \text{Vdp}_\text{SRC} \) on DP_CHG. If the ACA detects DN_CHG greater than \( \text{Vdat}_\text{REF} \), then it is allowed to close its Charger Switch for as long as VBUS_CHG remains above \( \text{Votg}_\text{sess}_\text{VLd} \). Note that this could result in the ACA drawing more than \( \text{ICfg}_\text{Max} \) from a PS2 port.
If the Charger Port was attached to a CDP, then it's possible that DN_CHG may go below $V_{DAT\_REF}$ of the ACA due to charging currents causing the CDP ground to be lower than the ACA ground. It's also possible that the CDP could issue a USB reset. The ACA shall ignore either of these effects, and continue to leave its Charger Switch closed. When VBUS_CHG goes below $V_{OTG\_SESS\_VLD}$, then the ACA is required to again check for VDN_CHG being greater than $V_{DAT\_REF}$, before opening the Charger Switch.

The Micro ACA is required to have a capacitance of $C_{MACA\_VBUS}$ on both the VBUS_OTG and VBUS_ACC pins. The reason for this is so that attached devices which support the Attach Detection Protocol (ADP) defined in OTG 2.0 can detect when they are attached to an ACA.
6.2.7 Portable Device State Diagram

Figure 6-4 shows the state diagram for a PD attached to an SDP, CDP, DCP, Micro ACA, ACA-Dock or B-device.

Each bubble represents a state of the PD. The first row in each bubble is the state number.

The first term in the second row indicates whether the attached device is acting like a Charging Port. The second term in the second row indicates what would be attached to the Accessory Port of the ACA, if the PD is attached to an ACA. The third row indicates whether or not the attached device is driving the PD VBUS pin. The fourth row indicates what resistance the attached device is applying to the PD ID pin. In state 2, the fifth row indicates that the ACA-Dock is outputting a voltage of \text{VDM\_SRC} to the D- pin of the PD.
In state 1, the PD detects that it is not attached to anything, or that it is attached to something that is not driving VBUS or pulling ID low.

In state 2, the PD is attached to an ACA-Dock that is driving VBUS. If the PD is removed from the ACA-Dock, or if the ACA-Dock stops providing VBUS, the PD transitions to state 1. An ACA-Dock is required to let its ID pin float if it is not driving VBUS. If the ACA-Dock were to ground the ID pin while it was not driving VBUS, then the PD would incorrectly transition to state 7, where it would attempt to drive VBUS into the ACA-Dock.

In state 3, the PD is attached directly to an A-device, or to an ACA that has an A-device on its Accessory Port. In either case, the PD is drawing current from the A-device, and not from the ACA Charger Port. This is why the second row has the term !Chg. If the A-device presents itself to the PD as a CDP, then the PD can draw IDEV_CHG from the A-device.

In state 4, the PD is attached to an ACA that has a charger on its Charger Port, and an A-device on its Accessory Port. Detaching the PD from the ACA causes the PD to transition to state 1.

In state 5, the PD is attached to an ACA that has a charger on its Charger Port, and does not have an accessory on its Accessory Port.

In state 6, the PD is attached to an ACA that has a charger on its Charger Port, and a B-device on its Accessory Port. Detaching the PD from the ACA causes the PD to transition to state 1.

In state 7, the PD is attached to a B-device, or to an ACA that has a B-device on its Accessory Port. This is the only state in which the PD is required to output power on VBUS. In states 2 to 6, the PD is able to draw power from VBUS.
6.3 Standard ACA

6.3.1 Standard ACA Ports

Figure 6-5 shows the ports of a Standard ACA.

Various cables can be used to attach the Accessory Port of a Standard ACA to an accessory, including:
- Standard-A to Micro-B
- Standard-A to Standard-B
- Standard-A to captive

A Standard ACA shall have one of the following mechanical interfaces for its Charger Port:
- Micro-B receptacle
- Captive cable terminating in a Standard-A plug
- Captive cable terminating in a charger
Table 6-3 Standard ACA Connectivity Options

</tbody>
</table>

An ACA does not allow data communication through the Charger Port. The ACA only allows charging from the Charger Port when a Charging Port is attached. It does not allow charging from the Charger Port whenever an SDP or an OTG device is attached.

In the case where both an OTG device and a B-device are charging from the Charger Port, it is not necessary to support SRP, since VBUS is already asserted at both the OTG Port and Accessory Port.

The OTG device is required to limit the current it draws from the ACA such that VBUS_OTG remains above \( V_{ACA\_OPR} \) min.

6.3.2 Standard ACA Architecture

Figure 6-6 shows the architecture of a Standard ACA.

![Figure 6-6 Standard ACA Architecture](image)
The Charger Switch allows current to flow from VBUS_CHG and VBUS_OTG. Note that unlike the Micro ACA, the Standard ACA does not have an Accessory Switch.

The Standard ACA is required to have a capacitance of $CSACA_{VBUS}$ on the VBUS_OTG or VBUS_ACC pins. The reason for this is as follows.

The Accessory Port does not have an ID pin, since it uses a Standard-A receptacle. Thus, the Standard ACA cannot detect when a plug has been inserted into the Accessory Port, and therefore it cannot inform the OTG Device of such an attach event. If a Charging Port were attached to the ACA Charger Port, then the accessory would connect, and the OTG device could detect the connect event. If a Charging Port were not attached to the ACA Charger Port, then the OTG Device would either have to leave VBUS asserted, or it would have to do ADP. In order to allow ADP to work, the combined capacitance on the VBUS_OTG and VBUS_ACC pins needs to be $CSACA_{VBUS}$.

The Adapter Controller performs several functions. These functions include:

- outputting a state onto the ID_OTG pin, ($RID_{GND}$, $RID_{A}$)
- using the DP_CHG and DN_CHG pins to detect if a Charging Port is attached to the Charger Port
- controlling the Charger Switch

### 6.3.3 Standard ACA Modes of Operation

The operation of the Standard ACA is shown in Table 6-4, and is described below. The table assumes that an OTG device is always attached to the OTG Port.

<table>
<thead>
<tr>
<th>Row</th>
<th>Charger Port</th>
<th>Accessory Port</th>
<th>Charger Switch</th>
<th>ID_OTG</th>
<th>OTG Device</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>non-charger</td>
<td>nothing</td>
<td>open</td>
<td>$RID_{GND}$</td>
<td>A-dev</td>
</tr>
<tr>
<td>2</td>
<td>non-charger</td>
<td>B-device</td>
<td>open</td>
<td>$RID_{GND}$</td>
<td>A-dev</td>
</tr>
<tr>
<td>3</td>
<td>charger</td>
<td>nothing</td>
<td>closed</td>
<td>$RID_{A}$</td>
<td>A-dev</td>
</tr>
<tr>
<td>4</td>
<td>charger</td>
<td>B-device</td>
<td>closed</td>
<td>$RID_{A}$</td>
<td>A-dev</td>
</tr>
</tbody>
</table>

Notes

1) Open refers to the high impedance state of the switch. Closed refers to the low impedance state of the switch.

When a PD is attached to a Standard ACA, the ID_OTG pin is either at $RID_{GND}$ or at $RID_{A}$, and the PD is always acting as an A-device.
6.3.4 Implications of not Supporting Standard ACA Detection

The OTG supplement only defines the floating and ground states on the ID pin. The floating state is any impedance greater than 1M, and the ground state is any impedance less than 10Ω. Since the RID_A is between the floating and ground resistance values, an OTG device that does not support ACA detection could interpret this value as either floating or ground.

If an OTG device interpreted the RID_A resistance as floating, then:
- it would not be aware of the opportunity to draw IDEV_CHG from VBUS
- it would default to peripheral, when it should default to host

6.3.5 Standard ACA Requirements

A Standard ACA Charger Port shall draw less than ISUSP when anything other than a Charging Port is attached to it.

A Standard ACA Accessory Port shall draw less than ISUSP when a Charging Port is attached to the ACA Charger Port and nothing is attached to the OTG Port or Accessory Port.

The resistance between VBUS_CHG, and either VBUS_OTG or VBUS_ACC of a Standard ACA shall be RACA_CHG_OTG when the Charger Switch is closed in Table 6-4, and the voltage on VBUS_CHG is at VACA_OPR.

The resistance between the internal ground of the Standard ACA and the ground pin of a Micro-AB receptacle attached to the OTG port of an ACA shall be ROTG_ACA_GND. This requirement limits the difference between OTG and ACA ground under conditions of high charging current. This in turn allows the OTG device to reliably detect the ACA ID resistance under conditions of high charging current.

When a Standard ACA detects VBUS_CHG asserted, it shall output VDP_SRC on DP_CHG. If the ACA detects DN_CHG greater than VDAT_REF, then it shall close its Charger Switch for as long as VBUS_CHG remains above VOTG_SESS_VLD. Note that this could result in the ACA drawing more than ICFG_MAX from a PS2 port.

If the Charger Port was attached to a CDP, then it's possible that DN_CHG may go below VDAT_REF of the ACA due to charging currents causing the CDP ground to be lower than the ACA ground. It's also possible that the CDP could issue a USB reset. The ACA shall ignore either of these effects, and continue to leave its Charger Switch closed. When VBUS_CHG goes below VOTG_SESS_VLD, then the ACA is required to again check for VDN_CHG being greater than VDAT_REF, before opening the Charger Switch.
